Lecture 16 - revision for weeks 1-6

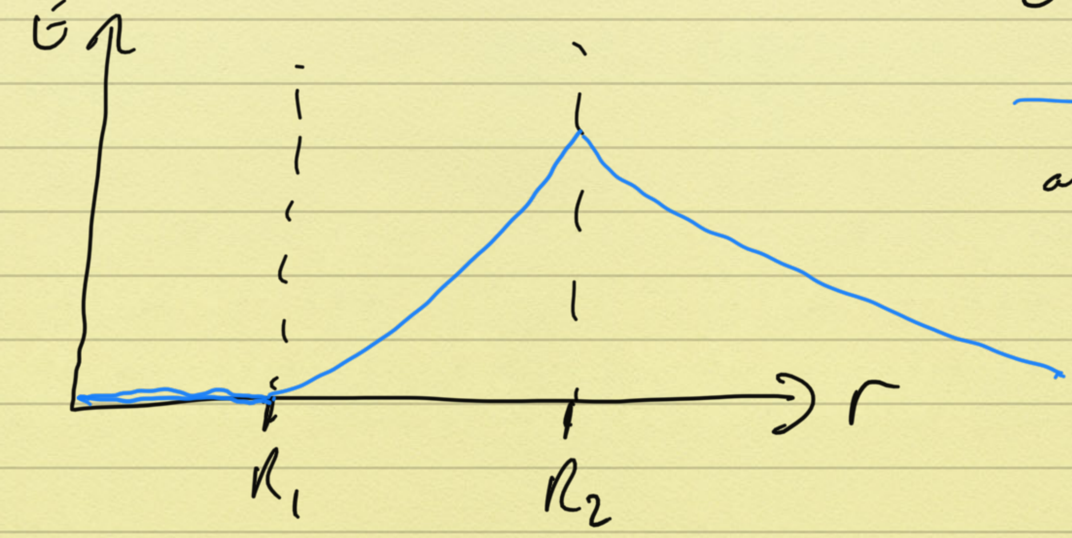
(Continued)

$\boxed{\text{Ex } 16.3}$

$R_1 < r < R_2$

$E = E_0\left(r^2 - \frac{R_1^3}{r}\right)$

(b)



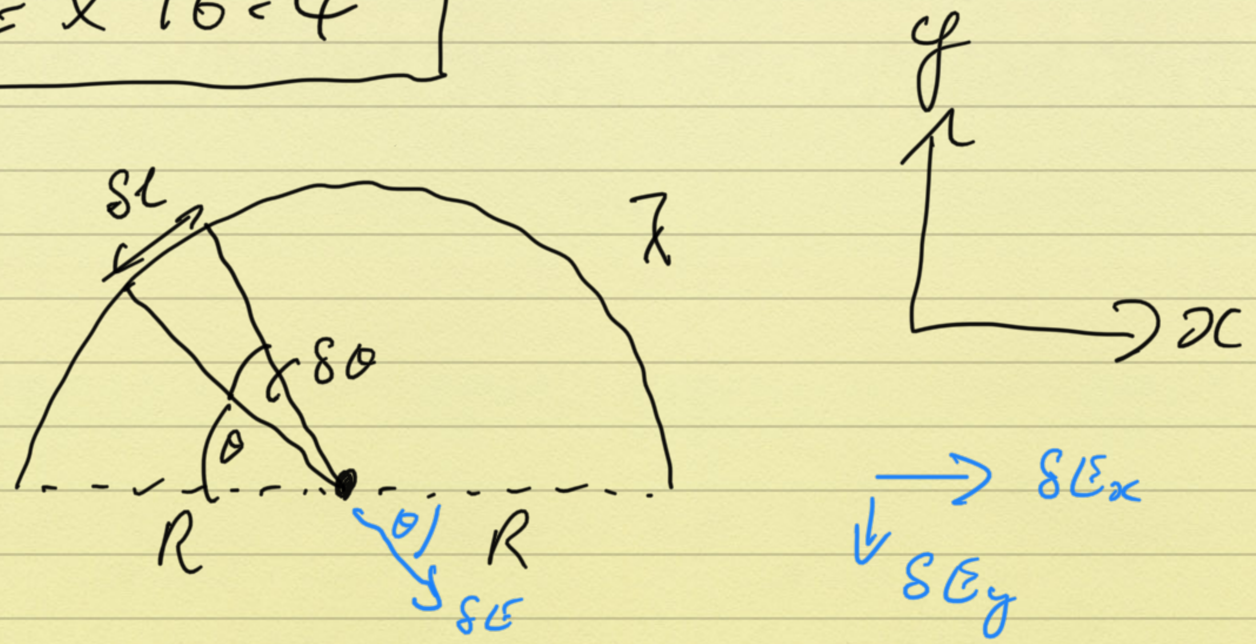
at $r = R_1$
$E = 0.$

(c) $V \quad (r > R_2)$ $\qquad E = \frac{\rho_0}{3\varepsilon_0}\left(R_2^3 - R_1^3\right)\frac{1}{r}$

$$V = -\frac{\rho_0}{3\varepsilon_0}\left(R_2^3 - R_1^3\right)\int \frac{dr}{r}$$

$$= -\frac{\rho_0}{3\varepsilon_0}\left(R_2^3 - R_1^3\right)\ln r + C$$

$\boxed{Ex\ 16.4}$



Coulomb's law.

$$\delta E = \frac{\lambda \, \delta l}{4\pi \varepsilon_0 R^2}$$

By symmetry x-component cancels out leaving just a y component in the negative y-dir^n.

Just consider magnitude!

$$\delta E_y = \frac{\lambda \, \delta l}{4\pi \varepsilon_0 R^2} \sin\theta$$

$$\delta\theta = \frac{\delta l}{R} \Rightarrow \delta l = R\,\delta\theta$$

$$\delta E_y = \frac{\lambda \, \delta\theta}{4\pi\varepsilon_0 R} \sin\theta$$

$$|\underline{E}| = \frac{\lambda}{4\pi\varepsilon_0 R} \int_0^{\pi} \sin\theta \, d\theta$$

$$= \frac{\lambda}{4\pi\varepsilon_0 R} \Big[-\cos\theta \Big]_0^{\pi}$$

$$= \frac{\lambda}{4\pi\varepsilon_0 R} \times 2 = \frac{\lambda}{2\pi\varepsilon_0 R}$$

$$\underline{E} = -\frac{\lambda}{2\pi\varepsilon_0 R} \, \hat{\underline{y}}$$
